Introduction to R for Data Management and Analysis

Marcel Ramos, MPH

Thursday, June 6, 2019

Notes on last week's lecture

- Using `c()` with mixed data types
- `...` ellipses
  - additional arguments to "lower level" functions (e.g., `par()` in `plot()`)
- '+' in the console indicates 'waiting for additional input...'
- relative vs absolute paths
  - when to use them?
- Any questions?

Brief recap

- Basic features of the language
  - interactive and *interpreted*
    - commands are entered in the console / via script
    - the commands are pre-processed in some way before evaluation
  - case sensitive, ignores spaces except between objects and functions
  - an object is any type of variable stored in R (i.e., `data.frame`, `numeric` vector, `function`, etc.)
  - Be familiar with the parts of a function
    - function name, argument, inputs
  - know your help pages (use `?functionname` or `help("functionname")`)
  - Finding help and troubleshooting are critically important
    - check for examples online
    - ask on the #rstats Slack channel
  - Help pages can be intimidating but useful

Today's lecture overview

- Importing and Exporting Data
- Classes and Data types in R
  - `data.frame`
  - data type coercion
- Subsetting
  - using brackets and dollar signs (`[`, `$`)
  - using vector operands
- More troubleshooting

Importing and Exporting Data

- Recognizing file types
  - File extensions (e.g., `.tsv`, `.csv`, `.xlsx`, `.txt`, `.sav`, `.sasb7dat`)
- Show file extensions on Windows
  - Windows File Explorer > View tab > Show File Extensions
- Downloading files from the internet
  - `read.csv()`
  - `download.file()`

Packages for reading foreign data

- readr, readxl, haven
- readr - provides fast and efficient read-in for large files
- readxl - allows you to read MS Excel files (`.xls`, `.xlsx`)
- haven - support for SPSS, SAS, and other data

Exporting Data

- `write.table()`
- `write.csv()` / `write_csv()`
- `write_delim()`

Classes in R

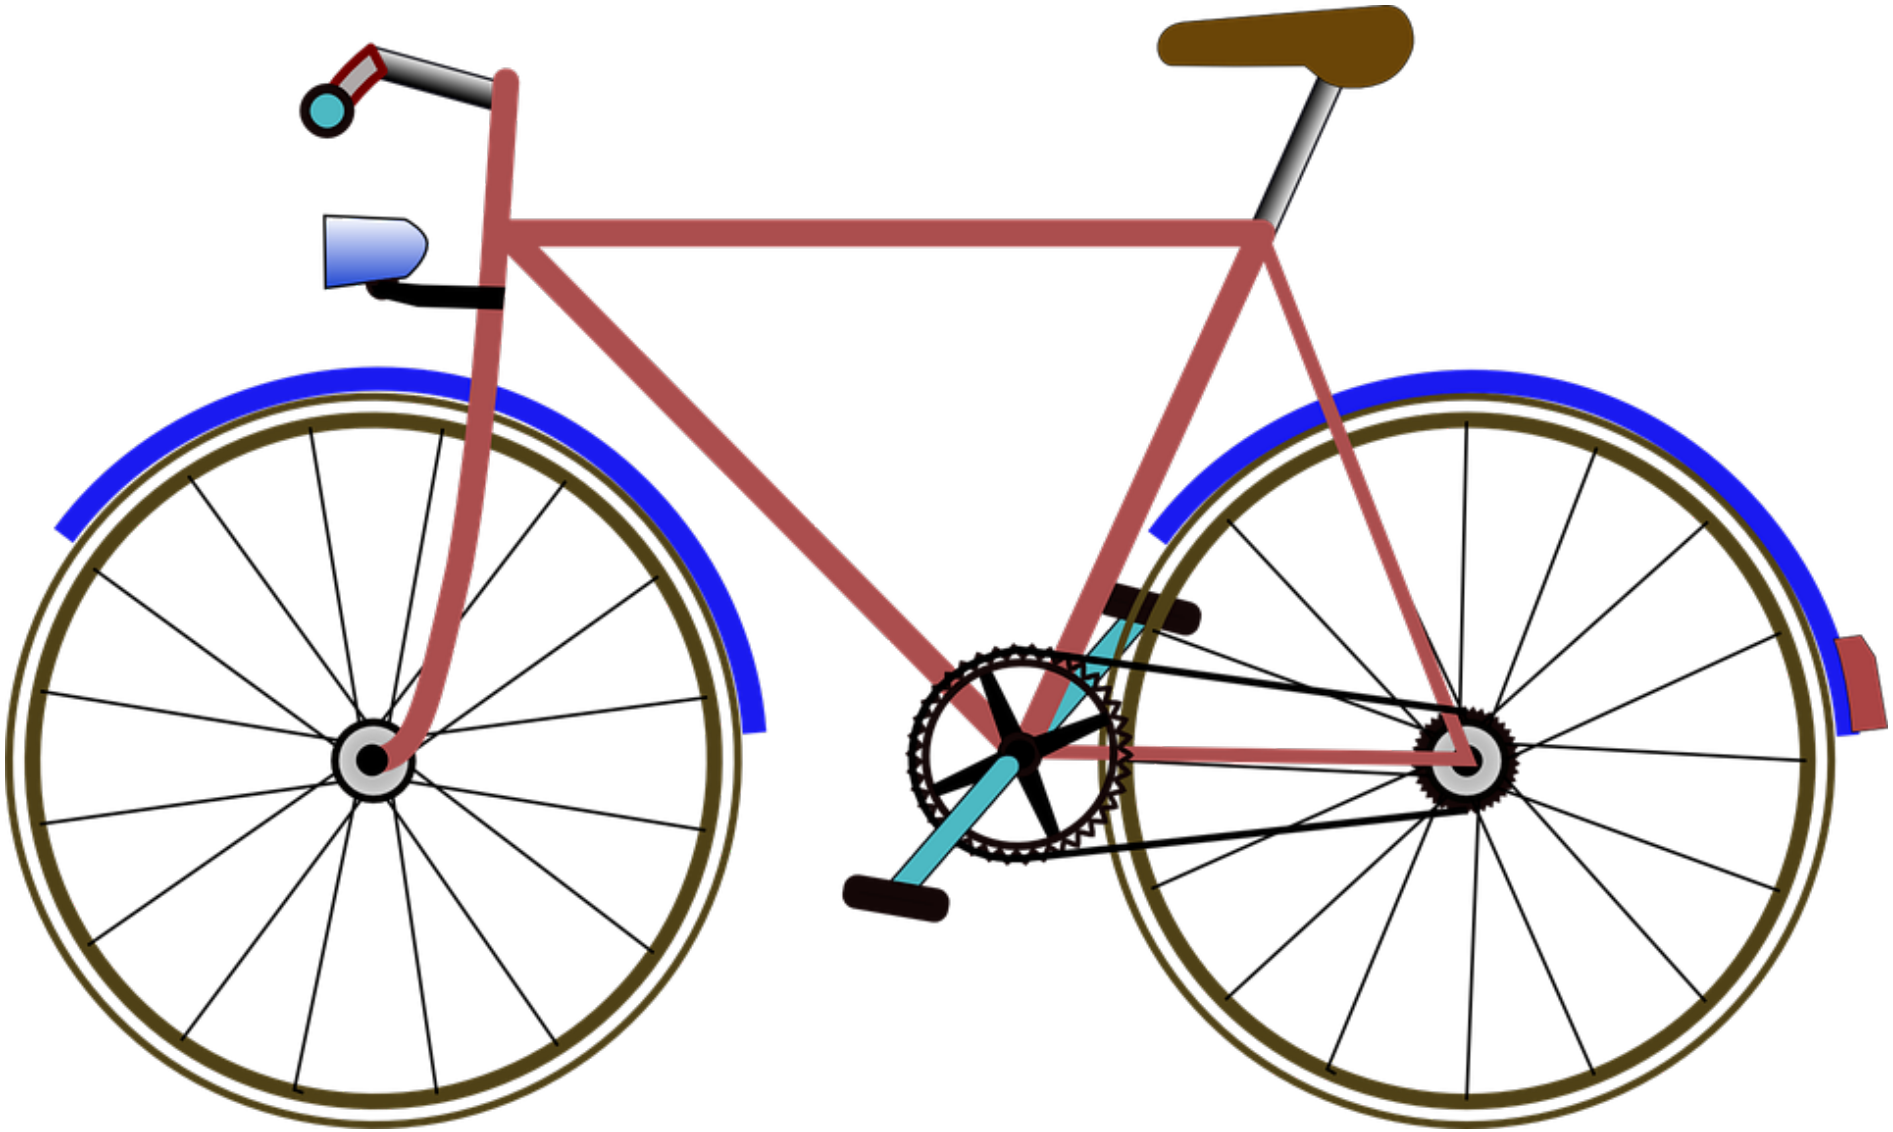

Figure 1: Bicycle

What are classes?

- R objects have class attributes
- Define what functions/operations can be performed
- `class()` function
- Examples

Vectors, classes, and functions

- Vectors of class (may be named):
  - character, integer, numeric, logical, complex, raw (bytes)
  - factor: discrete levels
    - mostly used in regressions
    - set reference by `releveling` categories
    - `relevel` does not work with ordered factors
  - missing (`NA`)
- Tabular classes:
  - `data.frame`
  - `matrix`
- Non-tabular:
  - `function`
  - `list`
  - `array`
  - custom classes

list

- Handle multiple data types in one
- Can contain vectors, data.frames, and even functions
- The `data.frame` is a special type of list

data.frame

- A unique type of list with uniform lengths in all elements
- Great for data analysis
- Most common class you will use to do analysis

matrix

- can handle only one type of data at a time
- can be character or numeric
- create using `matrix()` function

tibble

- custom tabular data class
- 'tidyverse' representation of a data.frame
- a neat print output
- metadata on the columns (chr, int, etc.)

Type (class) coercion

- as.___*(class type here)*___
- `as.character`
- `as.numeric`
- `as.logical`
- `as.data.frame`
- `as.tibble` (in 'tibble' package)

Exploratory functions on a data.frame

- head
- tail
- dim
- colnames
- rownames
- sapply(x, class)
